ABSTRACT

Fruits are perishable horticultural crops grown in tropical and sub-tropical areas of the world. It is a richest source of micro nutrients and phyto chemicals that contributed a significant role in human health. Mango, avocado, papaya, guava and pine apple are popular and economically important tropical fruits due to their essential nutritional properties and appreciated eating quality. However, in developing countries, upto 50% of those fruits are lost after harvest due to improper post-harvest handling practices. Edible coating, dip in calcium chloride solution, hot water treatment and drying are easily applicable post harvest treatments used in the preservation of such tropical fruits. Shelf life of mangoes coated using edible coating material can be extended up to 18 days without rotting and developing unpleasant-flavour relative to coated guava, papaya, avocado and pine apple fruits. Dipping harvested fruits in various concentration of calcium chloride solution exhibited different storage life. Consequently, mango fruits treated with 10% of calcium chloride solution preserved for 30 days at 12°C and 85-90% relative humidity. Guava fruits treated by hot water at 45°C for 3 minute lasts upto 31 days under room temperature. In this review maximum shelf life up to 9 months was found for Avocado fruit dried using freeze drying method.

Keywords: Fruits; edible coating; calcium chloride; hot water treatment; drying.

1. INTRODUCTION

Fruits are Perishable horticultural crops that contain high amount of water (75-90%) by wet basis. Most fruits are grown in tropical and sub-tropical areas of the world and are used of income generation for those who engaged in its production. Global production of tropical fruits were estimated to 100 million tonne since 2018 with increasing more than 8 million tonne from 2017 production year [1]. From this total of world tropical fruit production developing countries share estimated to 99 % of production annually.

Most tropical fruits have played a significant role in human diet in terms of nutritive and medicinal values. Fruits are also a richest source of micro nutrients (vitamins and minerals) as well as phytochemicals. Mango, avocado, papaya, guava and pine apple are popular and economically important tropical fruits due to their nutritional composition (vitamins, minerals, fiber and other phytochemical compounds) and appreciated eating quality (attractive colour, sweet taste and pleasant flavour).

Major limitation of these tropical fruits on marketing, storage and transportation are extensive post harvest loss and shorter shelf life. Post harvest losses of fruits are occur at all stages of post harvest operation, starts immediately after the time of harvest to its final destination due to improper post harvest handling practices [2]. Thus, Post harvest losses of fruits are estimated 5-20% in developed countries and 20-50 % in developing countries ( Mashav, 2010). Therefore, harvested fruits could be subjected to different post harvest treatments in order to preserve and ensure availability of such tropical fruits during marketing, off season and storage.

In developing countries, application of several advanced post harvest loss reduction mechanisms are important for mitigating food insecurity. Post-harvest treatments will slow down the physiological processes in fresh fruits such as respiration, senescence and ripening to prolong the shelf life of fresh commodities [3]. Plenty of technologies like Hot water treatments, edible coating, post harvest thermal treatments, dipping in food grade chemicals and other non thermal treatments have been applied on several fruit for preserving their physicochemical quality and reducing losses during post harvest life. Therefore, this article is aimed to summarizes some post harvest treatments applied on selected tropical fruits and its impacts on their respective shelf life.

Post harvest physiology of fruits: Harvested fruits are considered as a living organism because their metabolic functions continues during post harvest life [4]. These fruits undergo different physiological processes like respiration, ripening and senescence that must be controlled to extend products shelf life. Improper management of such metabolic processes of harvested fruits during storage can contributed to a major losses in both quantitative and qualitative. Respiration is the metabolic processes which utilizes oxygen to breakdown stored organic materials (carbohydrates, proteins, and fats) into simple end products with a release of energy. Increased respiration rate results accelerated ripening and senescence that shorten product shelf life.

There is a possibilities of extended product storage life by modification of the internal gas composition of storage atmosphere that minimizes the fruits respiration rate. “Ripening is part of the natural senescence of the whole fruits. It is an irreversible process that contributes to changes in chemical composition, skin color, total soluble solids, flavour and texture. It improves the fruit eating quality and shortened the post harvest life. Ripening and natural senescence of fruits can be delayed by lower temperature, elimination of mechanical damage and reducing ethylene production” [5].

Shelf life: Shelf life is the period of time that food products retained its microbial safety, nutritive value and sensorial attributes begins from the time the food is manufactured to its starts of deterioration. During this period, a food product remained acceptable without significantly, losing its sensory, chemical, physical, functional, microbiological and nutritional properties under different radiation, gas concentration, redox potential, packaging material and storage condition [6]. Proper temperature and relative humidity are critical to obtain an extended shelf life of stored fruits. When harvested fruits stored at higher than critical temperatures set for recognized produce, the storage life will be shortened. Similarly, if harvested fruits are stored at a lower than critical temperatures set by scientific organization for selected produce, their shelf life could affected by either freezing or chilling injury.

Edible coating: “Edible coatings are thin layers of edible materials and environmentally safe
technology that can be applied by dipping, spraying or painting on different fruits and vegetables. It controls moisture transfer, oxygen or carbon dioxide migration and oxidation processes to improve the mechanical integrity or handling characteristics of the food" [7]. In addition, “edible coatings help to preserves color, texture and volatile compounds of fresh fruits, maintains the structural integrity and protects against mechanical damages” [8]. Edible coatings has a major advantage of extending the shelf life of food products, control material exchange, enhancing safety, improve nutritive value, sensory attributes and attractiveness of food products because of active ingredients incorporated to food matrix during coating [9,10].

“The success of edible coatings for fresh products totally depends on the control of internal gas composition” [8]. Several Specific requirements described for edible coating by Arvanitoyannis and Gorris, [11] are manifested that “it could have good barrier to water, not deplete oxygen or build up excessive carbon dioxide, A minimum of 1–3% oxygen is required a to avoid a shift from aerobic to anaerobic respiration, reduce water vapor permeability, carry active agents (antioxidants, vitamins, etc.) and retain volatile flavor compounds, melt above 40°C without decomposition, easily emulsifiable, never interfere with the quality of fresh fruit, should have low viscosity and be economical”.

Different types of edible coatings can be prepared from protein, carbohydrate, lipid materials and their derivatives. Edible coating also contain food grade plasticizers, additives, antioxidants and antimicrobial compounds that can be applied to many fruits and fruit products. Carbohydrate based edible coatings like polysaccharides, starch, modified starch, chitosan and pectin are commonly used among natural bio polymer. Edible coatings processed from cassava starch applied to strawberries were contributed efficiently in reducing respiration rate, delaying weight loss, firmness loss and retained its sensorial acceptability during storage period [12].

Protein based edible coatings have good film forming properties and good adherence to hydrophilic surfaces. Lipid based edible coatings are the hydrophobic, block the transport of moisture and water vapor, improve surface appearance, maintain quality attributes and prolong the post harvest life of some fruits. Waxes are the most efficient lipid based edible coatings substances to decrease the water vapor pressure and was the first coating used in fruits specially in citrus fruits.

“Increased shelf life at least three days relative to uncoated fruit were reported by Gallo et al. [13] for guava fruit coated in immersion solution consisting between 5 and 10% of Potato starch, sodium alginate, carrageenan, pectin and glycerol between 10 and 30% at 50°C, then dried at 50°C for 30 minutes stored at 25°C and 50% Relative humidity”. “The potato starch and pectin based coatings are highly efficient and good in the preservation of the sensorial characteristics of the fruit (size, yellow colour and aroma) with 15 days” [13].

Shelf life of waxed mango fruit exceeds upto four days than non waxed mango fruit exhibited shelf stable upto 15 days that stored at room temperature [14]. According to research finding by Srinivasa et al. [15] mango fruits stored in chitosan covered boxes indicated an extension of shelf life up to 18 days and without any microbial growth and off-flavour. Extended shelf life upto 13 days was recorded for Papaya fruits treated with 5% of wax emulsion while 9 days noted for untreated papaya fruit stored at room storage condition [15].

Avocado fruits coated with gelatin-corn starch films have shown increased in shelf-life by reducing moisture migration, gas exchange and delaying over ripening [16]. In addition, pine apple treated using Alginate-based edible coating containing 0.3 percent (w/v) lemongrass showed extended shelf life for 10 days by arresting physiological changes of pine apple fruits stored at 10°C and 65 percent relative humidity [17]. “Gellan edible coating composed of gellan gum 0.56 % (w/v), glycerol 0.89 % (w/v) and sunflower oil 0.025 % (w/v) considerably lowers the respiration rate, reduces weight loss, and preserves the stiffness, colour, and sensory attributes of freshly sliced pineapple in low-temperature conditions. After 16 days of storage at 5 °C, there was no significant difference in the pH, titratable acidity, and TSS of coated and untreated samples. Cut pineapple can be kept fresh for a long time in the refrigerator with the help of the gellan edible coating solution" [17].

**Calcium chloride treatments:** Post harvest application of calcium may delay senescence in fruits with no detrimental effect on consumer
acceptability. Calcium chloride application on harvested fruits could have valuable role to prevent mechanical and physiological damage on fruit by making fruit cell walls hard and inhibit enzyme production of fungi and bacteria that cause fruit rotting [18]. Shelf life upto 15.32 days was observed for papaya fruits treated with 3.0% of CaCl₂ as compared to untreated fruits attained shelf life of 9 days [15]. Similar research report by priyanka et al. [19] showed that Papaya fruits treated in CaCl₂ at 2 percent extended the shelf life of fruit more than 9 days of storage.

In other way, Guava fruits treated for 2 to 4 minutes in 1% and 2% of calcium chloride recorded a potential shelf life of more than 9 days under room storage condition [20]. According to Galvis et al. [21] extended shelf life upto 30 days was noted for mango fruits dipped in 10% of calcium chloride solution at ambient temperature and stored at 12°C and 85-90% relative humidity. Similarly, Calcium chloride (CaCl₂) treatment significantly reduced relative weight loss, delayed the development of purple skin colour, blemishes, disease incidence and severity in avocado fruits stored for 18 days compared to untreated control [22].

Calcium chloride (CaCl₂) can also change intracellular and extracellular processes that can slow down fruit ripening, maintain cell walls so that it can inhibit fruit softening, and reduce mechanical and microbiological damage [23]. Mold incidence and severity appeared on pineapple dipped in the CaCl₂ solution after the 16th day of storage but it exhibited better sensory properties, particularly on texture, color, and overall acceptance After storage for 40th days [24]. Extended shelf life was reported by Youryon and Wongs [25] for Pineapple fruits immersed in 1%, 2% and 3% of CaCl₂ solution and kept under mild low temperature storage condition.

**Hot water treatment:** Hot water treatments are post harvest thermal treatments that applied on fruits by immersion, rinsing and brushing at desired temperature ranges and duration for retaining quality and microbial safety of fresh fruits. It is effective, particularly for fungal pathogen control because fungal spores and latent infections are either on the surface layers or under the peel of the fruit. The application of hot water treatments on different fruits have been increased in order to disinfections of insect pests, prevent fungal rots and increase fruit resistance to chilling injury [26].

The use of hot water as a disinfestations and maintaining quality of fresh fruits are affected by number of factors including maturity stage, cultivar type, temperature and duration [27]. Many fruits tolerate exposure to water temperatures of 50–52°C for up to 3 minutes, but shorter exposure for not more than 30 seconds at 55-60°C temperatures can control fungal storage rot [28]. In contrast, hot water dips for fruit require 90 min exposure to 46°C. Several Authors reported that hot water treatment of fruits at different temperatures for several minutes to hour were applied for maintaining fruit quality during marketing and storage [29-31].

Hot water treatment of mango fruits resulted reduced post harvest decay, improved color, appearance of mango fruits [32]. Mango fruit preliminarily treated with hot water significantly maintained firmness during 7 days of storage at ambient conditions [33]. Hot water treatment could reduce disease incidence and maintain postharvest quality during storage and prolong the shelf-life of papaya fruit [34]. Extended storage stability and marketability was reported for Pineapple and avocado fruits treated by hot water at different temperature and time combination [35,36]. Related research finding revealed that Guava fruits treated with hot water at 45°C for 3 minute lasts upto 31 days under room temperature of 5±2°C and 85 to 90 per cent relative humidity [37].

**Drying:** Drying is one of the oldest, simple, cost effective, safe and wide spread methods of food preservation. It removes a large amount of water contained in products so that the growth of micro-organisms and reaction lead to deterioration are inhibited [38]. It also reduces the weight and bulk of fruits which reduces transport and storage costs. Successful and appropriate fruit drying techniques produce healthy dried fruit products with good flavor, texture and color. Despite, drying does not improve food quality to obtain desired preservation and good quality of dried products sort and select the best-quality of fruits for drying [39,40,41].

**Solar drying:** Solar drying is the most effective method of drying foods using solar energy and in use in many parts of the world [42]. It is cheaper as it has little or no equipment costs and the produce has to spread on suitable surface and allowed to dry in the sun [43]. Fruits dried in the solar dryer are placed on trays made of screen or wooden dowels, stainless steel, teflon coated
fiberglass or plastic. Solar drying technology seems to be one of the most promising alternatives to reduce the post-harvest losses, extend shelf life with much preserved colour and texture [44-46]. Mangoes and pineapples dried in different solar drying and stored in low and high density polyethylene packaging containers could last up to more than six months [47].

**Freeze-drying:** Freeze-drying, also known as lyophilisation, or cryodesiccation, is a water removal process typically used to preserve a perishable Agricultural commodity or make the commodities more convenient for transport and storage [41,48]. Freeze-drying works by freezing the material and then reducing the surrounding pressure to allow the frozen water in the material to sublime directly from the solid phase to the gas phase. Freeze drying (FD) is the best method of dehydration as it gives a final product of the highest quality without heat compared to other methods of food drying [49]. Different fruits dried under freeze drying method exhibited improved color and maximum retention of vitamin C, chlorophyll, flavor and taste [50-52].

Fruits dried under modern freeze dryer have a longer shelf life without releasing as much of their nutritional content and sensory characteristics [53]. High-quality with preserved color of Pollock avocado powder to be used in various food application was obtained using freeze drying method [54]. Avocado fruit dried using freeze drying method has a shelf life of up to 9 months with exhibited slight changes in nutritional quality and sensorial properties [55].

According to Patel et al. [56] guava fruits were effectively preserved for long time with low adverse health effects when subjected to freeze drying condition. Similar research finding reported by Jangam et al. [52] revealed that freeze-dried mangoes, avocados and pineapples retained their sensory characteristics and shelf stabilities. The very low water content of freeze dried fruits helps them to have a longer shelf life [57]. However, freeze dried fruits have a high moist air absorption tendency and additional barrier to water absorption solutes such as Arabic gum, tricalcium phosphate and maltodextrin should be added to increase its shelf stability [58,59].

2. CONCLUSION

Application of different post harvest treatments to fruits are highly encouraged to preserve and reduce their post harvest loss. Appropriate edible coating materials, hot water treatment, dip in optimum concentration of calcium chloride solution and drying under suitable drying methods are easily applicable post harvest treatments used in the preservation of perishable tropical fruits. Those post harvest treatments have considerable role in ensuring fruits shelf stability, up to 9 months.
